Chapter 1 INTRODUCTION

GENERAL INFORMATION

The 9866A Printer may be used to print characters which are input to the printer from a control device such as an -hp- 9800-Series calculator. The Model 66 Printer is capable of printing 80 characters (in a 5 x 7 dot matrix) on a single line at a rate of 240 lines per minute with a line density of six lines per inch. Table 1-1 is a complete listing of the Model 66 Printer Technical Specifications.

Table 1-1. Technical Specifications.

Printing Speed:	240 lines/minute
Print Density:	80 characters/line 6 lines/inch (2.4 lines/cm)
Character Set:	64 alphanumeric characters* (including space)
Character Font:	5 x 7 dot matrix
Data Input Format:	7 line ASCII code, bit-parallel, character-series fashion
Printer Paper:	8-3/4" wide thermal sensitive paper, available in 250' rolls
Size:	17-3/4" x 16" x 6-00 " (45.09 cm x 40.64 cm x 15.21 cm)
Weight:	45 lbs. (20.39 kg)
Power Requirements:	Nominal Voltage ranges: 100, 120, 220, 240V ac; +5% to -10% of each range Frequency range: 48 to 66 Hz Power: 250 voltamps, maximum
Temperature Range**:	0°C to 45°C
Humidity Range**:	95% relative humidity maximum (non-condensing)

*All characters are not available with some calculator systems.

**The printer paper is sensitive to high temperature and high humidity conditions.

SCOPE OF THE MANUAL

This manual provides the information which is necessary for the installation, interfacing, or repair of a printer. Information describing printer operations when controlled by 9800-series calculators may be found in the Operating Manuals listed in Table 1-2. It is assumed that personnel servicing the printer are familiar with the necessary printer operating information for the calculator/printer system being serviced.

Table 1-2. Printer Control Operating Manuals

Calculator	Manual	Manual P/N	*Printer Control Section P/N
9810A	11264A Peripheral Control I	09810-90008	09810-90080
9810A	11252A Peripheral Control II	09810-90010	09810-90080
9820A	11220A Peripheral Control I	09820-90027	09820-90019
9820A	11224A Peripheral Control II	09820-90024	09820-90019
9830A	Operating & Programming	09830-90001	N/A

*This part number may be used to order Model 10 or Model 20 printer control operating sections.

SERVICE CONCEPT

Depending upon which printer assembly is defective, one of two methods should be used to service the printer. Procedure A applies to the electronic chassis components, the Low Voltage Power Supply (A3) assembly, and the Motor Drive (A5) assembly. Procedure B applies to the Input Logic (A1), Control Logic (A2), High Voltage Power Supply (A4), Row-data Storage (A6), Printhead (A7), and Heatsink assemblies.

PROCEDURE A

Detailed information describing the chassis, A3, and A5 electronic assemblies is provided to assist servicing personnel in the repair of these assemblies to a component level. These assemblies may be either repaired at the customer's location or exchanged with the corresponding

SERVICE CONCEPT (cont'd)

PROCEDURE A (cont'd)

11291A service kit assembly. The defective assembly may then be repaired at a convenient location or replaced with a new replacement assembly.

PROCEDURE B

All of the electronic assemblies except the chassis, A3, and A5 assemblies are on the HP Blue Stripe Exchange Program. When defective, these assemblies should be exchanged with the corresponding 11291A Service Kit assembly and the defective assembly returned to CSC or PCE for credit.

THE 9866A SERVICE KIT - 11291A

The 11291A Service Kit is available through CSC (PCE in Europe) to assist in the repair of defective printers. The Troubleshooting and Repair chapter of this manual provides information that allows the most effective use of the service kit. Table 1-3 lists the 9866A electronic assemblies which are provided in the service kit.

Table 1-3. The 11291A Service Kit Assemblies

Assembly	-hp- Part Number Assembly
A1	09866-69501 Input Logic (Blue Stripe Program)
A2	09866-69502 Control Logic (Blue Stripe Program)
A3	09866-66503 Low Voltage Supply
A4	09866-69504 H.V. Supply (Blue Stripe Program)
A5	09866-66505 Motor Drive
A6	09866-69506 Row-Data Storage (Blue Stripe Program)
A7 (2)	09866-67908 Printhead (expense item)
A8	09866-60006 Heatsink Assembly (expense item)

2-1**Chapter 2
INSTALLATION****POWER REQUIREMENTS**

Two line-voltage selector switches (see Figure 2-1) mounted on the rear panel of the printer will, when correctly positioned, permit the printer to be operated on a line voltage of either 100V, 120V, 220V, or 240V ac (+5%, -10%). The line frequency must be within a range of 48 to 66 Hz, inclusive. A maximum power of 250 voltamps is required for normal printer operation.

Figure 2-1. The Rear Panel

Figure 2-2. Switch Settings for the Various
Nominal Powerline Voltages**CAUTION**

A DIFFERENT FUSE IS REQUIRED AT EACH OF THE TWO VOLTAGE RANGES OF 100-120 VAC and 220-240 VAC. SEE "FUSES" FOR FURTHER INFORMATION.

FUSES

Table 2-1 shows the fuse that must be installed prior to connecting the printer to the ac power source.

FUSES (cont'd)

Table 2-1. Powerline Voltages and Fuses

NOMINAL VOLTAGE	OPERATING RANGE (-10%, +5% of nominal)	9866A FUSE
100 volts	90 to 105 volts	3-amp Slo-Blo
120 volts	108 to 126 volts	3-amp Slo-Blo
220 volts	198 to 231 volts	1.5-amp Slo-Blo
240 volts	216 to 252 volts	1.5-amp Slo-Blo

WARNING

BEFORE CHANGING A FUSE, ENSURE THAT THE PRINTER IS DISCONNECTED FROM ANY AC POWER SOURCE.

CAUTION

THE 9866A MAY BE DAMAGED IF THE INCORRECT FUSE IS INSTALLED.

◆◆◆◆◆ GROUNDING REQUIREMENTS ◆◆◆◆◆

To protect operating personnel, the National Electrical Manufacturers' Association (NEMA) recommends that the printer's cabinet be grounded. The printer is equipped with a three conductor power cable which, when connected to an appropriate power receptacle, grounds the cabinet of the printer.

◆◆◆◆◆ CALCULATOR/PRINTER CONNECTIONS ◆◆◆◆◆

AC POWER

The printer's ac power cord may be plugged into any unused calculator convenience power outlet or any convenient ac power outlet.

2-3CHAPTER 2
INSTALLATION

CALCULATOR/PRINTER CONNECTIONS (cont'd)

AC POWER (cont'd)

NOTE

The printer uses 3 amps of current when operated on 100 or 120 Vac. Therefore, when the printer is connected to one of the calculator convenience outlets, the maximum current available for additional peripherals is limited to 3 amps during 100V or 120V operation.

PRINTER SIGNAL CABLE CONNECTIONS (OPT 10, OPT 20, or OPT 30 only)

When ac power has been properly applied to the printer, the Signal (i.e., I/O) cable may be connected to the cannon connector located on the rear panel of the printer. The cable is connected by aligning the keys in the cable's connector with the key slots in the printer's cannon connector. Then, while pushing the two connectors together, rotate the knurled barrel on the signal cable connector clockwise; thus drawing the two connectors together and locking them in place.

NOTE

The signal cable used to connect the printer and Model 30 Calculator uses a cannon connector on both ends. Either end of the cable may be connected to the printer.

If a Model 10 or Model 20 calculator is being used to drive the printer, then switch the calculator OFF and connect the remaining end of the signal (I/O) cable to any one of the unused calculator I/O slots.

NOTE

The Model 30 Calculator has a cannon connector located on the rear panel for printer connections. This connector should be used to attach the signal cable to the calculator using the same procedure described for the printer signal cable connections.

CALCULATOR/PRINTER CONNECTIONS (cont'd)

SETTING THE SELECT CODE (OPT 10 or OPT 20 only)

The select code (or address) of the peripheral device which is interfaced to the calculator through the interface kit, can be selected on the interface card. The recommended printer select code is 8.

The procedure given below should be used if a select code other than 8 is preferred.

1. Switch the calculator and the peripheral device OFF.
2. Disconnect the interface from the calculator. Remove the four screws located on the top of the card assembly; then, turn the card over and lift off the bottom cover.
3. Locate the Select Code Switch (see Figure 2-3). Raise the hinged cover on the switch. Using a small, flat-bladed screwdriver, carefully rotate the selector-tab until it is positioned at the desired select code number (numbers are printed on the side and on the top cover of the switch). Before closing the cover, be sure the slot in the selector-tab is positioned at a right angle with respect to the length of the switch.
4. Close the switch cover and replace the interface card bottom cover. Secure the cover with the four screws which were removed in step 2.
5. Place a Select Code Label on the peripheral device to indicate the new select code. A package of labels is supplied with the interface kit.
6. Reconnect the interface to the calculator, and turn the calculator and peripheral device ON. Verify that the desired select code is set by performing some peripheral control operations (or running a program) which specify the new code.

CALCULATOR/PRINTER CONNECTIONS (cont'd)

SETTING THE SELECT CODE (OPT 10 or OPT 20 only) [cont'd]

Figure 2-3. Setting the Select Code

 9866A PRINTER INTERFACING

The 9866A Printer may be used as an eighty-character 'line printer' in many applications. The following presentation provides information describing signal timing and voltage requirements which must be met to properly interface the printer to an initiating device.

The printer requires signals which are negative true (i.e., $\emptyset V$ ='low'=true; +5V='high'=false). The required voltage range of the low or $\emptyset V$ is $\emptyset V$ to +.8V; the required voltage range of a 'high' or +5V signal is +2V to +5.5V. The maximum amount of noise on a signal line must be within the specifications prescribed for TTL (Transistor-to-Transistor Logic) circuits.

Table 2-2 lists the signal which must be present on each of the interface cable wires; these signals are described in Figure 2-4. Table 2-3 provides a list of the -hp- ASCII characters which are in the printer vocabulary.

9866A PRINTER INTERFACING (cont'd)

Figure 2-4. 9866A Control Signals

SIGNALREQUIREMENTS

1. DATA

Data must be valid from t_1 to t_2 Data may be valid until t_4 Data is latched at t_1 2. $\overline{\text{CLB}}$

(optional)

 $\overline{\text{CLB}}$ must be false (high) before $\overline{\text{CTL}}$ (low) is given (t_1) $\overline{\text{CLB}}$ must remain false (high) until $\overline{\text{CTL}}$ goes high (t_3) $\overline{\text{CLB}}$ cannot clear printing process (t_4), but can otherwise clear all characters in printer if $\overline{\text{FLG}}$ is low.

9866A PRINTER INTERFACING (cont'd)

SIGNALREQUIREMENTS3. \overline{CTL} \overline{CTL} must go low to indicate data ready (t_1) \overline{CTL} must remain low (true) until \overline{FLG} goes low (t_2) $\geq 2\mu s$. \overline{CTL} must return low to indicate new data ready4. \overline{FLG} \overline{FLG} goes low (true) to indicate data received (t_2) \overline{FLG} is high to indicate 'printer ready' (t_0 and t_4) \overline{FLG} is low when printer is busy (5 μs to 250ms)

◆◆◆◆◆ RECOMMENDED CIRCUITS ◆◆◆◆◆

PRINTER OUTPUT CIRCUITS

Each output from the printer is driven by an open collector, inverting buffer/driver. The current sink of these drivers is 40mA and the breakdown voltage is +30V dc.

Vol @ ($I_{ol} = 16mA$) = +0.4V maximumVol @ ($I_{ol} = 40mA$) = +0.7V maximum

Voh (Open Collector) = 30V maximum

 I_{ol} = 40mA maximum I_{oh} @ (Voh max.) = 250 μA RECOMMENDED INTERFACE RECEIVING CIRCUIT

The preceding text describes the printer output signals. Since each printer output driver is an open collector, the receiving circuits of the interface must have a positive pull-up voltage (not to exceed +30V dc), and they must be restricted to less than 40mA printer-driver source current.

The circuit shown on the next page is a recommended interface receiving circuit.

RECOMMENDED CIRCUITS (cont'd)

Figure 2-5. Recommended Receiving Circuit

PRINTER INPUT CIRCUITS

The printer input signals, as described in the previous text, are negative true (i.e., $0V = \text{low} = \text{true}$). Each input signal is received by series 74 TTL Integrated Circuit with a resistive divider on each input line. The resistive divider sets a bias of approximately +3V when the input cable is disconnected. The input voltage must not exceed +5.5V dc.

The figure below represents the recommended interface transmitting circuits.

Figure 2-6. Recommended Transmitting Circuits

Chapter 3

THEORY OF OPERATION

THE PRINTING PROCESS

The printer is capable of producing up to eighty characters on a single line by utilizing a thermal process that essentially 'burns' selected dots in a 5 x 7 dot matrix, onto heat-sensitive paper. The selected dots in each 5 x 7 matrix are printed one five-dot row at a time until all seven rows are printed; thus, each of the eighty characters is created.

To lower the printhead's current and cooling requirements, all eighty characters are not printed at the same time. Instead, the dots necessary to print every fourth character (i.e., 20 total characters) in each row are printed. This necessitates the printing of each row, in part, four times to complete that row for all eighty characters. This process applies for each of the seven rows.

The printheads which are activated for printing during the first pass on each row are designated as the group 1 printheads (one group-row); those activated during the second pass are group 2, and so on for the four groups of printheads (see Figure 3-1).

Figure 3-1. The Character Grouping

After completion of the seventh row, the paper is automatically advanced three rows, thus positioning the paper to allow a spacing of three rows between each print line.

Adjacent to each logical step on the flowchart (Figure 3-3) is one or more assembly designators (see Table 3-1). These assembly designators indicate the pc assembly on which the logic operations occur. The arrows ('+') between assembly designators indicate that the operation command originates on the assembly with the first designator and the result occurs on the assembly indicated by the following designators.

Assembly Designator	Assembly Number	Description
A1	09866-69501	Input Logic
A2	09866-69502	Control Logic
A5	09866-66505	Motor Drive
A6	09866-69506	Row Data Storage

CHARACTER COMPOSITION

The input to the ASCII decoder is a 7-digit, ASCII-coded character from the calculator. The decoder translates the ASCII codes into 6-bit printer codes. (If the input code is not in the printer vocabulary, the input is ignored and a FLAG signal returned to the calculator.) The printer code is then loaded in a bit-parallel, character serial fashion into the 6 dynamic registers - one serial bit per register - until each register contains eighty bits. If the calculator does not output 80 characters, the printer fills the remaining characters with spaces. The dynamic registers are always filled from the left to the right as shown in example 1.

[†]These registers are 80-bit static MOS chips. The data in each register is recirculated during each print-mode shift operation, which is the reason for describing them as dynamic rather than static.

CHARACTER COMPOSITION (cont'd)

First Input

1	-	-	-	-	-
---	---	---	---	---	---

-	-	-	-	-
---	---	---	---	---

Second Input

2	1	-	-	-	-
---	---	---	---	---	---

-	-	-	-	-
---	---	---	---	---

Output

When data is not being input to the dynamic registers, the stored data may be output by shifting data through the register and 'sensing' the output bit (see Example 2). As the register shifts, the previously sensed bit loops back to the input and remains stored in the register. In this manner the data may be sensed as many times as necessary, and is not cleared until new data-inputting occurs.

	character number															
Fully Loaded Register*	80	79	78	77	76	75	}	{	7	6	5	4	3	2	1	Output
Register After First Shift	1	80	79	78	77	76	}	{	8	7	6	5	4	3	2	Output
Register After Second Shift	2	1	80	79	78	77	}	{	9	8	7	6	5	4	3	Output

Since printhead requirements allow only one of every four adjacent characters to be printed at one time, the dynamic registers must be shifted until the appropriate character can be sensed. This is accomplished by shifting the register four additional times. The twenty characters are sensed, encoded into the dot-row pattern required for printing (by the ROM decoder), then one dot-row is stored in the dot-row storage registers. The dynamic registers are then shifted four additional times after which the printing of one group-row occurs (See Figure 3-1C.)

(continued on page 3-6.)

*Each register contains one of the 6-bits which comprise one character.

3-4

Figure 3-1C. The Group Outputs

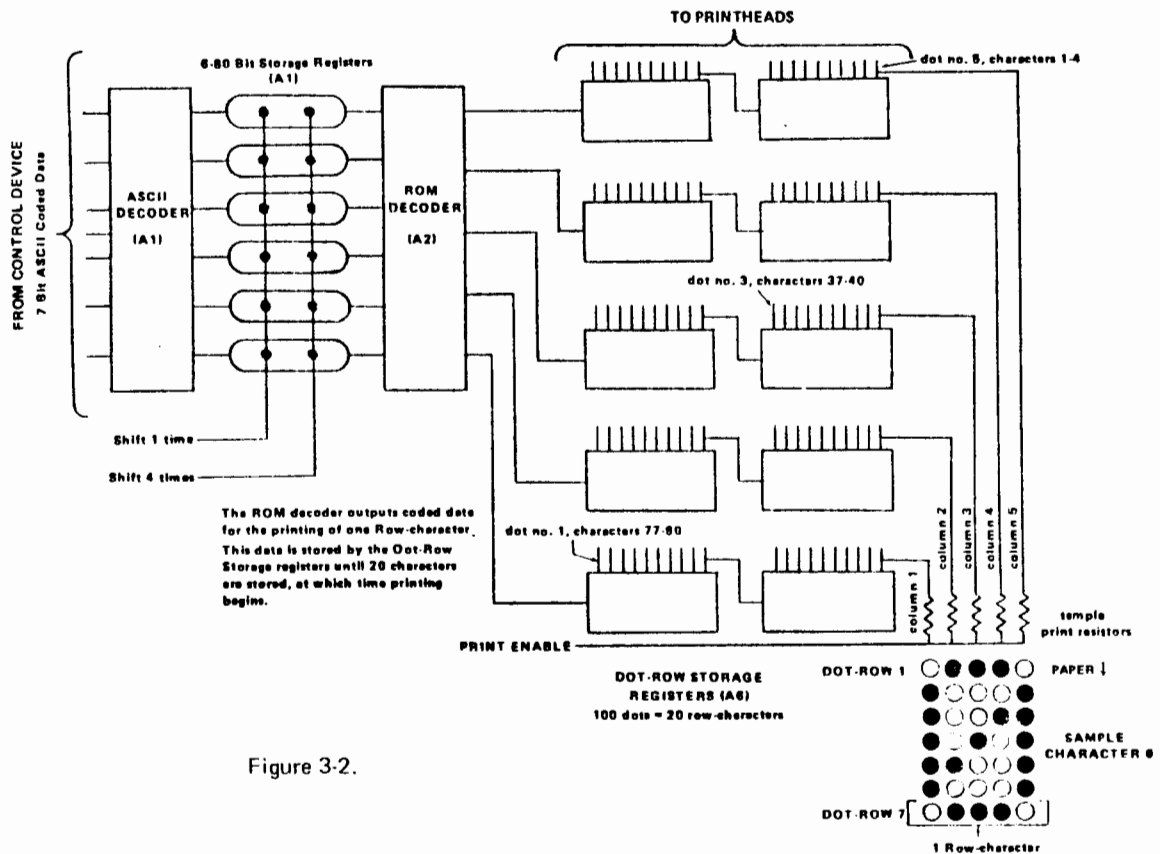

Figure 3-2.

GENERAL THEORY OF OPERATION (cont'd)

SEE PAGE 3-6
for a detailed flowchart
explanation.

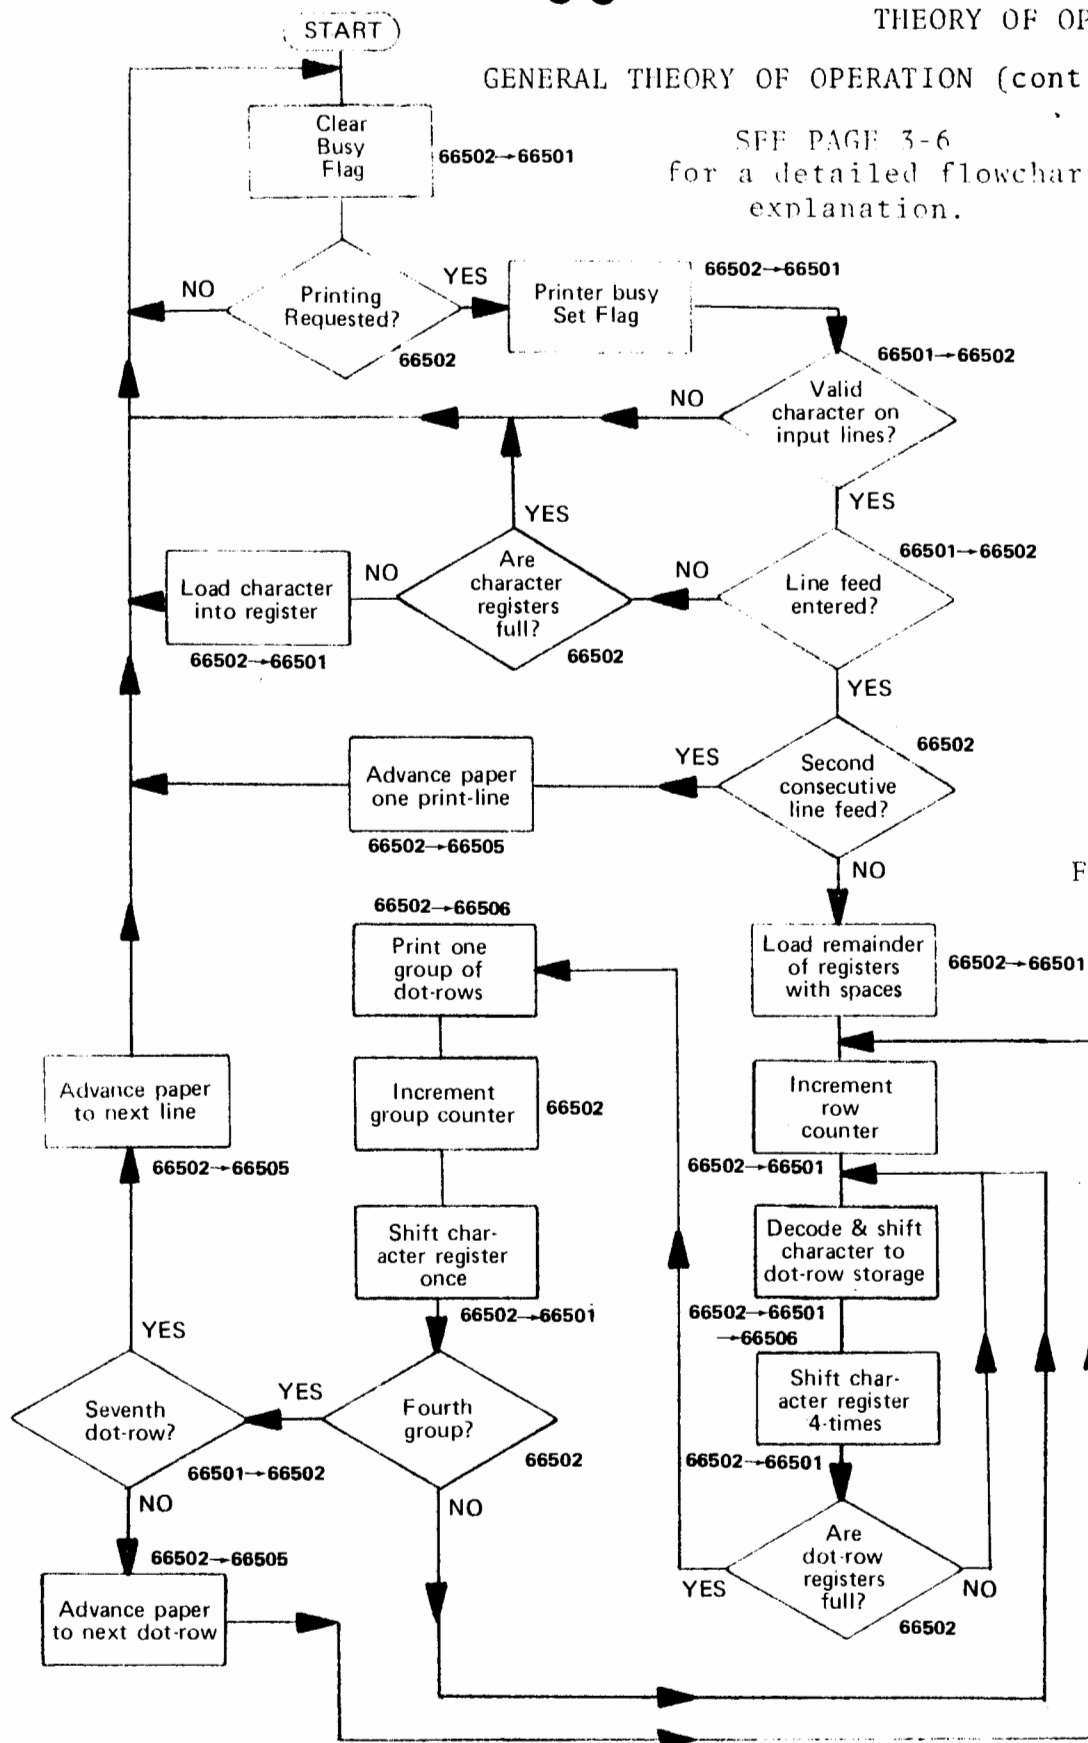

Figure 3-3.

GENERAL THEORY OF OPERATION (cont'd)

CHARACTER COMPOSITION (cont'd)

The dynamic registers are then shifted one more time to position them so that the first character in group two may be sensed. The group two characters are then processed in the same manner as group one.

When the first row of all four groups is printed, the data, in the dynamic registers, for group one is again accessed, encoded, stored and printed. The remaining five rows are printed in the same manner, which completes eighty characters with seven rows per character.

FLOW CHART EXPLANATION

Computer
Museum

Operation

Description

The Flag Flip-Flop is cleared, thus allowing new data to be input from the calculator. This occurs following each data input unless printing is occurring.

An ASCII character is on the input lines. The printer begins processing the new input and sets the Flag Flip-Flop. Thus, no new ASCII inputs can be entered.

The printer ensures that the requested (ASCII-coded) character is in its vocabulary (i.e., print set).

The printer checks to see if the new (ASCII-coded) character is a linefeed. (One 'linefeed' causes the row-counter to increment and printing to occur. Two successive 'linefeeds' cause the paper to advance 10 rows or one print-line.)

FLOW CHART EXPLANATION (cont'd)

Operation

Description

Before attempting to load the dynamic registers with another character, the registers are checked to see if 80 printable characters have been entered since the last line was printed. If the registers are full, the printer ignores all further character entries until a 'line-feed' causes the row-counter to increment and the line of 80 characters to be printed.

Since the dynamic registers do not contain 80 characters, the new (ASCII-coded) input character is loaded into the registers.

Two (or more) consecutive linefeeds result in the paper advancing one print line (10 rows).

If the line to be printed contains fewer than 80 characters the empty characters are filled with blank spaces. (These spaces are right-justified.)

The paper is positioned for printing of the first row.

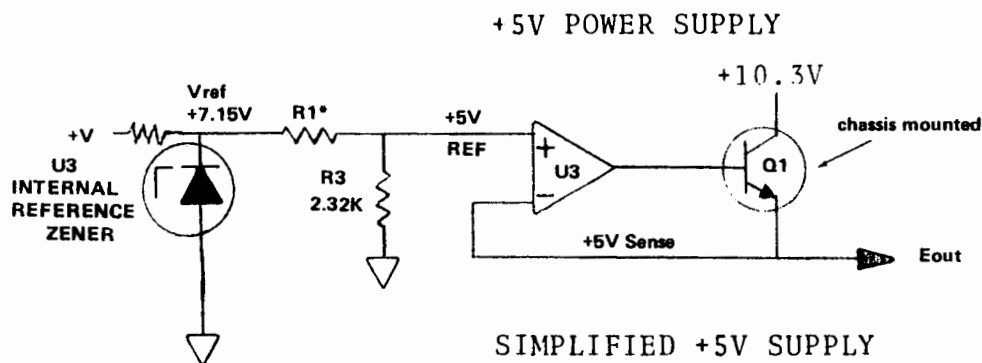

The 6 output bits (each character) of the dynamic shift registers are decoded by the ROM character decoder and output to the dot-row storage registers. The output of the ROM determines which dots in the (20) 5 x 7 matrix will be printed for each of the 20 (group) characters.

FLOW CHART EXPLANATION (cont'd)

Operation	Description
(cont'd)	The ROM outputs this information one group-row at a time, then increments to the second group. This process continues until all four groups (80 characters) have one row printed.
Are dot-row registers full?	When the dot-row registers are full, one group-row is ready for printing.
Print one group of dot-rows	One group-row is printed.
Increment group counter	The group counter steps from group 1 through group 4. Thus, each group-row is successively printed.
Shift character register once	The first character of a following group is output to the ROM decoder.
Fourth group?	The group counter is checked to ensure that all four groups are printed. The counter is then reset for another row.
Seventh dot-row?	The seventh dot-row completes one line. After printing seven rows the paper is advanced three dot-rows.

LOW VOLTAGE POWER SUPPLIES

Refer to the +5V Power Supply Schematic and the Simplified +5V Supply diagram (above) during the following presentation.

The +5V power supply regulator (U3) provides the correct amount of base drive-current for Q1 by comparing the reference voltage and +5V sense voltage. The reference voltage is provided by a temperature compensated reference zener that is contained in the regulator (U3). R1 and R3 reduce the +7.15V zener voltage to the +5V reference voltage. R1 must be changed to compensate for differences in the zener voltage when the regulator is changed.

The 'Series pass' transistor is chassis mounted to provide more adequate heat dissipation.

+5V POWER SUPPLY PROTECTION

Current limiting is provided by R10 and U4. R10 is in series with the +5V supply output; thus, the voltage across R10 is proportional to the 'series pass' transistor's (Q1) output current. U4 senses the voltage across R10 and switches the regulator OFF when the current output of Q1 becomes excessive.

Fuse F1 is a high speed fuse which protects 'downstream' devices should the series pass transistor become shorted.

LOW VOLTAGE POWER SUPPLIES (cont'd)

+5V POWER SUPPLY PROTECTION (cont'd)

Overvoltage protection is provided by CR10 and SCR Q2. When the supply output exceeds + 5V, CR12 fires Q2 which clamps the +5V output to ground. When ac power is switched OFF, Q4 is switched ON to shut down U3.

±12V POWER SUPPLIES

Power for the ±12V supplies is provided by two separate full-wave bridge rectifiers. The 12V supplies utilize self-contained regulators U1 and U2 to provide regulated ±12V outputs.

POWER ON PRESET (NPOP)

The Power On Preset (POP) circuit provides a low-true output to preset the printer logic when the printer is switched ON. The preset pulse is removed when the charge on C9 reaches the threshold of U5.

◆◆◆◆◆ MOTOR DRIVE ASSEMBLY (A5) ◆◆◆◆◆

The Motor Drive Assembly (A5) consists of four darlington amplifiers and their power supply. Each of the amplifiers is switched ON by a 0V input signal (on MDA1, MDA2, MDB1, or MDB2) from the Control Logic Assembly (A2). Two amplifier outputs are connected to each step motor winding; one amplifier provides positive drive-current and the other amplifier provides negative drive-current. (Only one amplifier per motor winding is activated at one time.) The two circuits containing Q1, Q3, Q5 and Q7 provide positive drive current; Q2, Q4, Q6, Q8, Q9, and Q10 provide negative drive current. CR1-CR4 protect the respective amplifiers from 'flyback current' when current through the winding is switched OFF.

EXAMPLE

When MDA1 is low, Q1 and Q5 are switched ON. (The Control Logic switched Q2 and Q6 OFF.) The positive current through the step motor winding (together with current through the second winding of the motor) causes

CHAPTER 3
THEORY OF OPERATION

MOTOR DRIVE ASSEMBLY (cont'd)

EXAMPLE (cont'd)

the motor to step (rotate) a preset amount and stop. The motor will remain at that position until the drive current to at least one of the motor windings is reversed.

POWER SUPPLY

Power for the amplifiers is provided by Z1, a full-wave bridge rectifier, which outputs $\pm 17V$ dc.

Chapter 4

ASSEMBLY ACCESS

DISASSEMBLY

Disconnect the ac power cord and printer signal cable, then proceed as follows:

1. Most of the printer assemblies may be accessed by removing the three black screws which are located in the back of the top cover, then removing the top cover. The removal of the two PC board retainer plates allows the removal of any PC assembly which is contained in the upper portion of the instrument.
2. Access to the Row-data Storage (A6) and Mother board (AØ) assemblies may be obtained by placing the instrument on the back panel feet and removing the six screws in the bottom cover. Once the bottom cover is removed, the A6 assembly (7 screws) or AØ assembly (6 screws) may be removed following the removal of the associated screws. It may be necessary to loosen the three screws which hold the left, bottom foot to the chassis before the AØ assembly can be removed. If these three screws are loosened, they should not be tightened until the bottom cover is replaced and the 6 screws are tight. (This is necessary to provide proper alignment.)
3. The following procedure should be used to replace one or more printheads.
 - A. Remove the top cover (see step 1).
 - B. Loosen the two screws in the top-front and bottom-front of the instrument which attach the front panel to the chassis (see figures 4-2 and 4-4), and pull the front panel out and to the side of the instrument. This provides access to the printhead assembly.

CAUTION

CARE SHOULD BE TAKEN TO AVOID BREAKING THE CABLE WHICH CONNECTS THE FRONT PANEL AND THE MAIN FRAME.

DISASSEMBLY (cont'd)

3. (cont'd)

- C. Remove the two screws in the bottom-front and top-front of the printhead assembly (see Figure 4-4). Then, lift the printhead assembly upward until the four printhead cables are extended. Use a small screwdriver (e.g., a #1010) to disconnect the four connectors from the A6 assembly. The screwdriver should be inserted into the slot in the front of each connector and gently turned until the connectors are forced apart.
- D. Loosen the two load screws which are associated with the defective head. If the load screws are removed, take care not to lose the spring inside of each screw (see Figure 4-6).
- E. Loosen the two associated #6 set screws (see Figure 4-4).
- F. Remove the defective printhead out the bottom of the assembly.

CAUTION

THE PRINTHEADS MAY BE DAMAGED BY THE ABRASIVE ACTION OF THE HEAD AGAINST ANOTHER HEAD OR HARD OBJECT.

- G. Use a brush to clean the reference edge (see Figure 4-1) of the heat sink assembly. Ensure that the reference edge is free from all dirt, grime, or metal burrs. If the reference edge cannot be properly cleaned, replace the heatsink assembly.
- H. When the printhead(s) is being installed in the printhead assembly, care should be taken to ensure that the bottom edge of the head is flush with the reference edge.
- I. Use the .004 inch spacer to adjust the spacing between each head. Always begin the spacing with one of the two center heads used as a reference and space the adjacent heads .004 inches from it. The remaining head should be spaced in relation to the head next to the reference head. Thus, the two outside heads are spaced last.
- J. Check to ensure that all eight #6 allen screws are tight and that each head appears to be properly aligned.

DISASSEMBLY (cont'd)

3. (cont'd)

J. (cont'd)

CAUTION

NEVER USE A ROUNDED #6 ALLEN WRENCH TO TIGHTEN THE
PRINthead ALLEN SCREWS.

- K. Reinstall the printhead assembly by reversing steps C through F. Ensure that the printhead cables are not jammed between the chassis or the roller and the printhead assembly.
- L. Perform the 'Printhead Alignment Procedure'.
- M. If the printhead cannot be properly aligned, recheck steps G through K. If the problem cannot be corrected, use Figure 4-1., the 9866A Bucket Assembly exploded view, to replace the Heatsink Assembly (A8).

CAUTION

DO NOT DISASSEMBLE THE HEAT SINK ASSEMBLY.

◆◆◆◆◆ PRINthead ALIGNMENT PROCEDURE ◆◆◆◆◆

1. Switch the printer line switch to the OFF position and remove the ac power cord.
2. Loosen the eight load screws (see Figure 4-4) approximately three turns.

PRINthead ALIGNMENT PROCEDURE (cont'd)

3. Connect the ET to the connector on the top of the H.V. Power Supply assembly (A4), and turn the knob on the ET C-CW to the stop. This reduces the voltage on the print resistors as they may be damaged by normal printing currents during the alignment procedure. Connect the ac power cord to the printer and switch the printer ON. Then, connect the printer signal (I/O) cable.
4. Continuously print an 80-character line. If a 9800-Series calculator is being used, then the 9866A Exerciser may be used for a continuous printout by performing the following step after the 9866A Exerciser has been loaded into the calculator memory:

9810A PRESS: GO TO LBL A SET FLG CONTINUE

9820A PRESS: SET FLAG Ø RUN PROGRAM

9830A PRESS: Ø for the number of times to perform the test.
5. While the printer is printing, turn the knob on the ET until printing is just visible. Then, adjust the two alignment cams (see Figure 4-1) for an optimum printout.
6. Tighten the eight load screws and check the printout. If three heads result in a satisfactory printout but the fourth head appears to be too light on one side, loosen the load screw on the dark side until the printout is even.
7. Turn the knob on the ET to the clockwise stop and again check the printout. If the printout is satisfactory, disconnect the ac power cord and reassemble the printer. Otherwise, repeat steps 5 through 7 until the printout is satisfactory.

PRINthead ALIGNMENT PROCEDURE (cont'd)

8. If a satisfactory printout cannot be obtained, step M of the 'Assembly Access' procedure provides information for the replacement of the heat sink assembly.

Due to a higher yield process, a new print head assembly is being used for the 9866A. The new print head (part no. 09866-69910) is identified by a green ceramic backing plate. The current print head has a black backing plate. 9866A Printers with the new print head are identified by a serial number prefix of 1426A. Although electrically and mechanically identical, an inadjustable difference in print contrast exists between the two heads. Always replace print heads with the same type (same color code) of head.

4-6

Figure 4-6. Printhead Removal

Chapter 5

TROUBLESHOOTING AND REPAIR

CHASSIS

WARNING

UNLESS OTHERWISE SPECIFIED, ALL AC POWER MUST BE REMOVED FROM THE 9866A FOR A MINIMUM OF 60 SECONDS PRIOR TO PERFORMING ANY TROUBLESHOOTING ON CHASSIS COMPONENTS. FAILURE TO OBSERVE THIS WARNING MAY RESULT IN ELECTRICAL SHOCK.

1. Disconnect the ac power cord and wait 60 seconds before proceeding with step number 2.
2. Remove the printer top and bottom covers.
3. Visually inspect the chassis for foreign, conductive materials and loose or damaged components. Ensure that the case of Q1 and Q2 is not shorted to the chassis. Make all necessary repairs of any defects which are found during the visual inspection.
4. Remove the A3, A4, and A5 PC assemblies. Then, disconnect the connector to the mother board (XA0). See Figure 4-3.
5. Use an -hp- 427A (or equivalent) to check Q1, Q2, and CR1. (Resistance reverse biased \geq 10X Resistance forward biased.) These components may be easily accessed on the XA0 and XA4 connectors (see "Chassis Wiring Diagram" on pp. 5-18). Ensure that C1 & C2 aren't shorted.
6. Check the full-wave bridge rectifiers, Z1 and Z2, for shorted or open diodes.
7. The power transformer, T1, may be checked by measuring the voltage on each secondary winding. Table 5-1 lists the ac voltage output of each winding. The ac power must be connected and the line switch in the ON position to perform this step.

CHASSIS (cont'd)

7. (cont'd)

WARNING

PRECAUTIONS MUST BE TAKEN NOT TO COME IN CONTACT WITH PRIMARY (AC) POWER WHEN CHECKING THE POWER TRANSFORMER OUTPUTS.

CAUTION

ALLOW AT LEAST 60 SECONDS FOR C1 AND C2 TO DISCHARGE BEFORE REINSTALLING ANY OF THE PC ASSEMBLIES.

Table 5-1. Open Circuit Secondary Voltages

TRANSFORMER OUTPUT	VOLTAGE (rms)
Blu-Blu	18.2V ac
Orn-Orn	18.2V ac
Grn-Grn	09.6V ac
Gry-Gry	38.0V ac
Yel-Yel	27.7V ac
Yel-Brn	13.8Vac
Voltage across C1	9.6V dc
Voltage across C2	52V dc

◆◆◆◆◆ LOW VOLTAGE POWER SUPPLIES (A3) ◆◆◆◆◆

NOTE

The following procedures assume that the replacement of a 9866A assembly with the associated service kit assembly corrects the failure.

LOW VOLTAGE POWER SUPPLIES (A3) (cont'd)

Before troubleshooting the A3 assembly, remove the PC board and visually inspect the board for damaged components or foreign, conductive materials. If any defects are found, they should be corrected before proceeding with the procedure.

+12V POWER SUPPLIES

Measure the +12V power supply outputs. If either of the supply outputs is not in the required specification ($12 \pm 5\%$), check the output of the full-wave bridge rectifier for 22.0V ($\pm 10\%$). If the full-wave bridge output does not meet the required voltage specifications, repair the bridge. If the full-wave bridge voltage output is satisfactory, replace the associated regulator IC (U1 or U2).

+5V POWER SUPPLY

To troubleshoot the +5V power supply, perform the following procedure.

1. Check A3Q1. Replace A3Q1 if it is suspected of being defective.
2. Check, and replace if defective: F1, CR12, and Q2.
3. Replace the voltage regulator, U3. It may be necessary to change R1* to bring the power supply output within the required voltage specifications. To select the proper value for R1, substitute a 2K ohm pot for R1. Adjust the pot for the correct power supply output, then, measure the resistance to which the pot is adjusted and use Table 5-2 to select the nearest resistor value to the resistance measured across the pot.
4. If the power supply is still defective, replace U4.

CHAPTER 5

TROUBLESHOOTING & REPAIR

LOW VOLTAGE POWER SUPPLIES (A3) (cont'd)

POWER ON PRESET CIRCUIT (POP)

1. Check CR8, 10, 13, 14, 15, & 17, and replace if found defective.
2. Check C8, C9, and C10 for shorts.
3. Replace U5.

MOTOR DRIVE ASSEMBLY (A5)

The following procedure assumes that the printer operates correctly when the 9866A A5 assembly is replaced with the appropriate 11291A kit assembly.

Visually inspect the A5 assembly for foreign, conductive material and loose or damaged components. If any defects are found, perform any repairs that are necessary.

The following procedure should assist you in the location of defective A5 assembly components.

1. Install the defective A5 assembly into the 9866A and switch the LINE switch ON.
2. Check for $\pm 17V$ dc output from Z1 (to ground).
3. Use an -hp- 427A voltmeter (or equivalent) to measure the dc voltage on the collectors of the large, heat sunk transistors (Q1 - Q4) while holding 'PAPER ADVANCE' pressed.

Result:	Button Pressed	Button Released
Q1 and Q3	+2.5V dc $\pm 10\%$	(+17V or -6V dc)
Q2 and Q4	-2.5V dc $\pm 10\%$	(-17V or +6V dc)

MOTOR DRIVE ASSEMBLY (A5) (cont'd)

4. If any of the voltages are incorrect, repair the associated amplifier. The two transistors in each darlington pair should be replaced together; the 'flyback' diodes CR1 through CR4 should be checked while the associated driver is removed.
5. If any doubt exists as to proper amplifier operation, an -hp- 180A oscilloscope (or equivalent) may be used to observe the waveform on the collector of Q1 through Q4 (shown below) while holding 'PAPER ADVANCE' pressed.

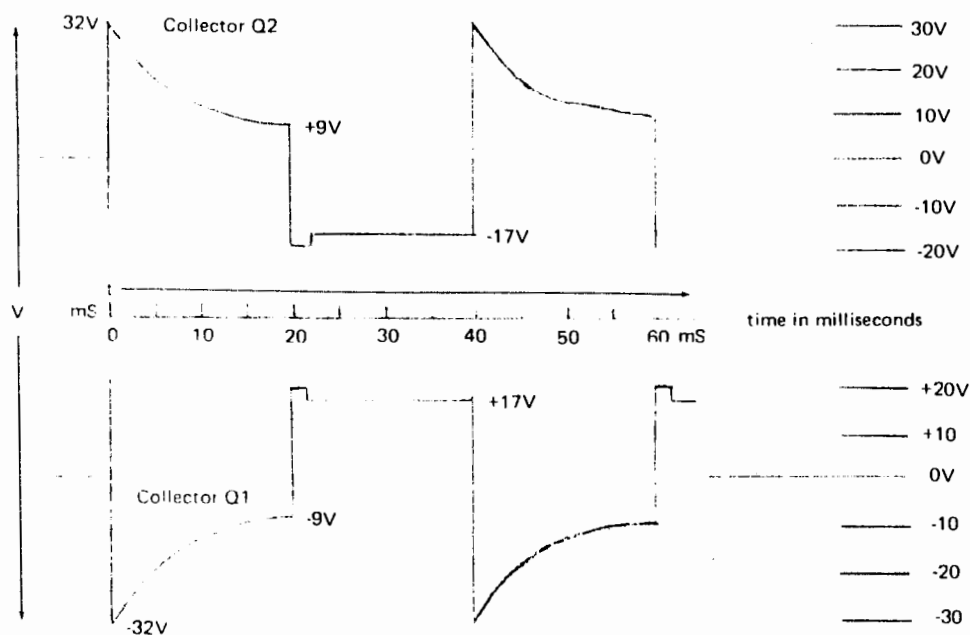

Figure 5-1. Motor Drive Waveform

6. If all four amplifiers are inoperative, either Z1, C1, or C2 is defective.

NOTE

The value of resistors A5R1-R4 has been changed from 15 ohms to 10 ohms to increase the torque developed by the motor. This change required that the wattage of those resistors also be changed from 10W to 20W.

RE: DRAWN
C-04925

Figure 4-1. 9866A Bucket Assembly

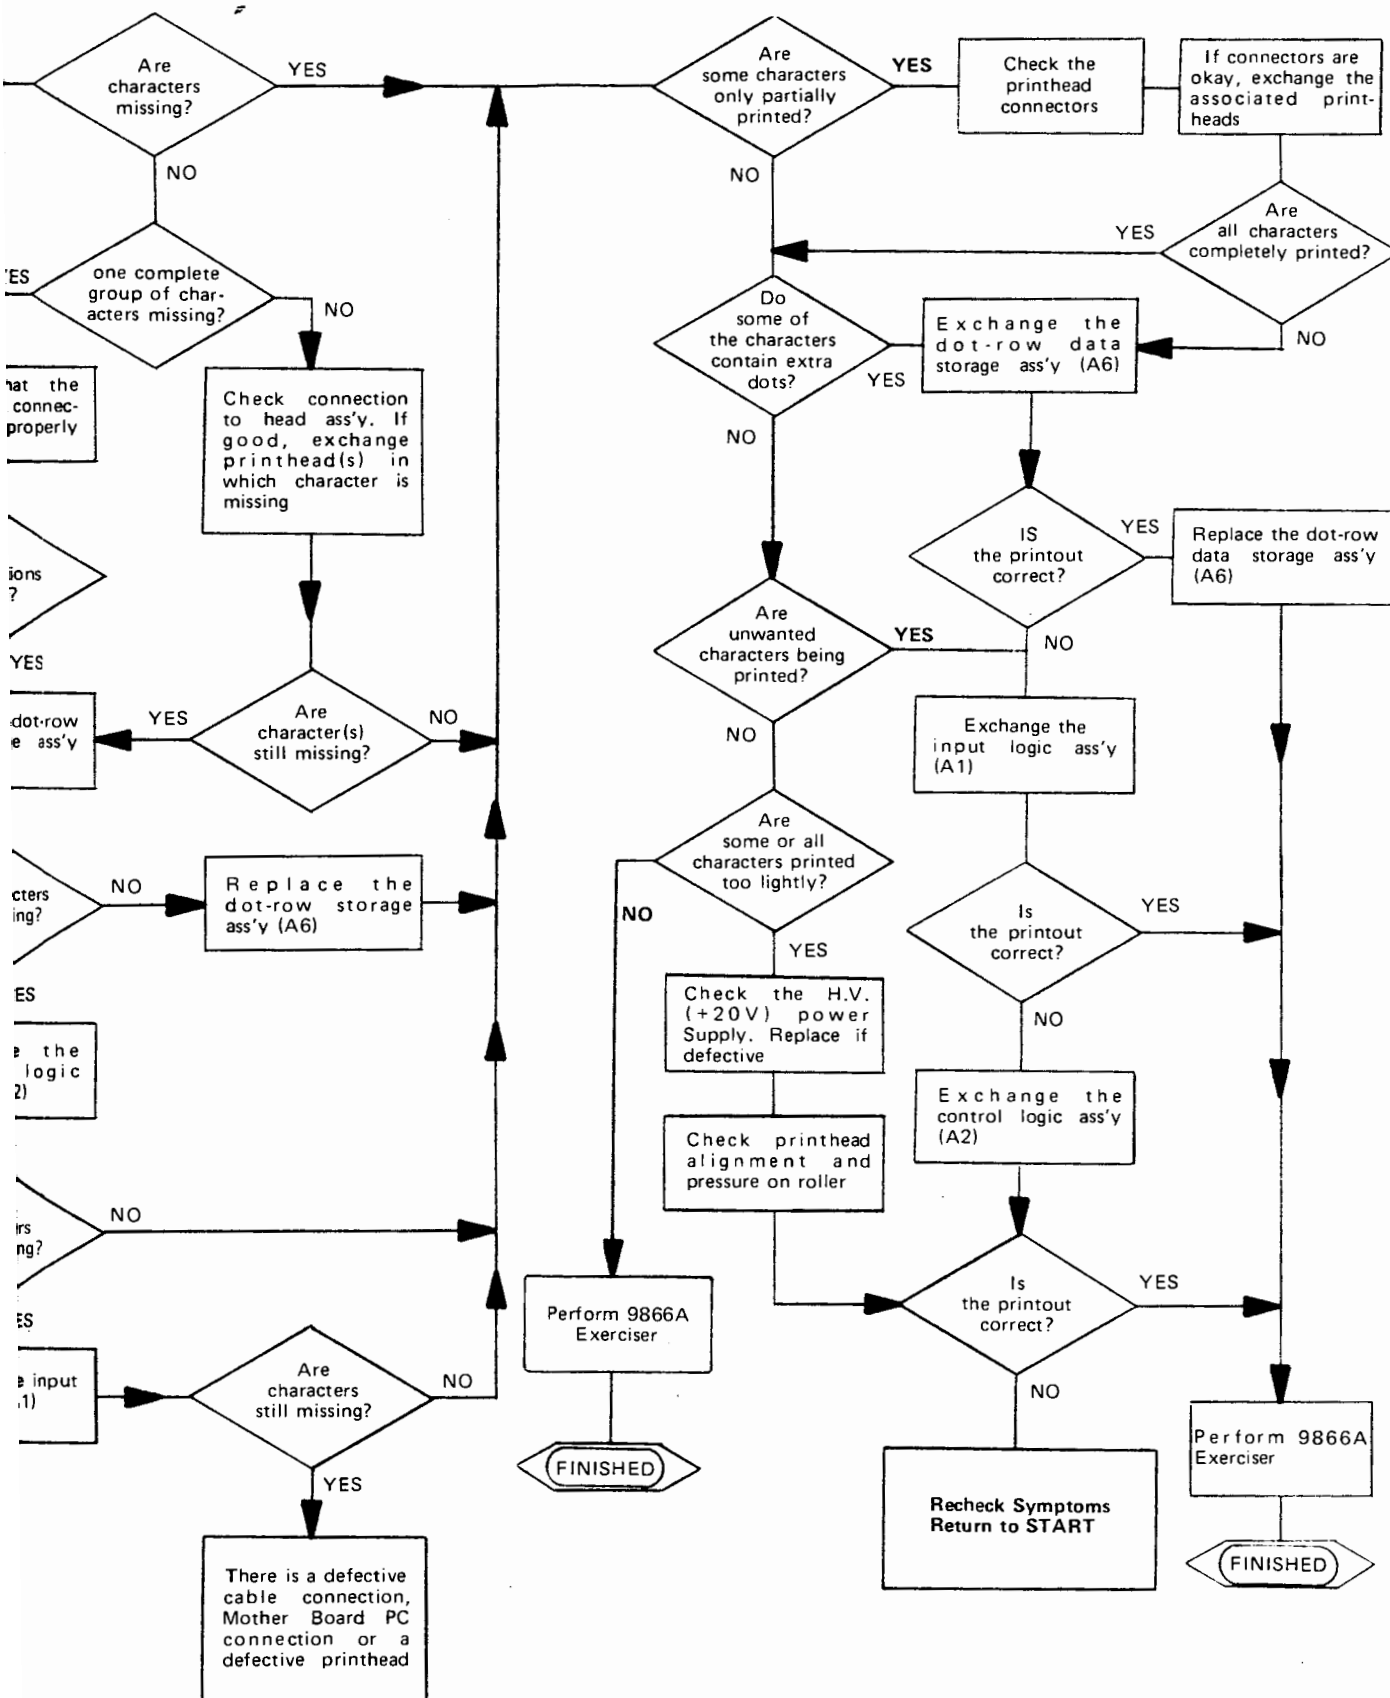

Figure 5-1.
9866A Troubleshooting Tree

NOTE: The Remainder of this procedure assumes that the power supply outputs are correct.

Press the 'Paper Advance' button

Repair the Motor Drive Ass'y (A5)

Does the paper advance properly?

YES

NO

Does the Drive Motor turn?

YES

The problem is mechanical

check motor drive for slippage

check paper rollers for binding

check the printhead pressure on roller

NO

Exchange the Motor Drive Ass'y (A5)

Does Motor turn when 'paper advance' is pressed?

YES

NO

Exchange the control logic ass'y (A2)

Does 'Paper Advance' operate properly?

YES

NO

Defective Drive Motor or Connector to Drive Motor

Can anything be printed?

YES

NO

Exchange dot-row data storage ass'y (A6)

Can anything be printed?

YES

Replace the defective dot-row storage ass'y A6)

NO

Exchange input logic ass'y (A1)

Can anything be printed?

YES

NO

Exchange the control logic ass'y (A2)

Can anything be printed?

YES

NO

Defective connection to printheads or connector on mother board is defective

YES

Ensure that printhead connectors are properly seated

All connections good?

NO

YES

Exchange dot-row data storage ass'y (A6)

Are characters still missing?

YES

Exchange control logic assembly (A2)

Are characters still missing?

YES

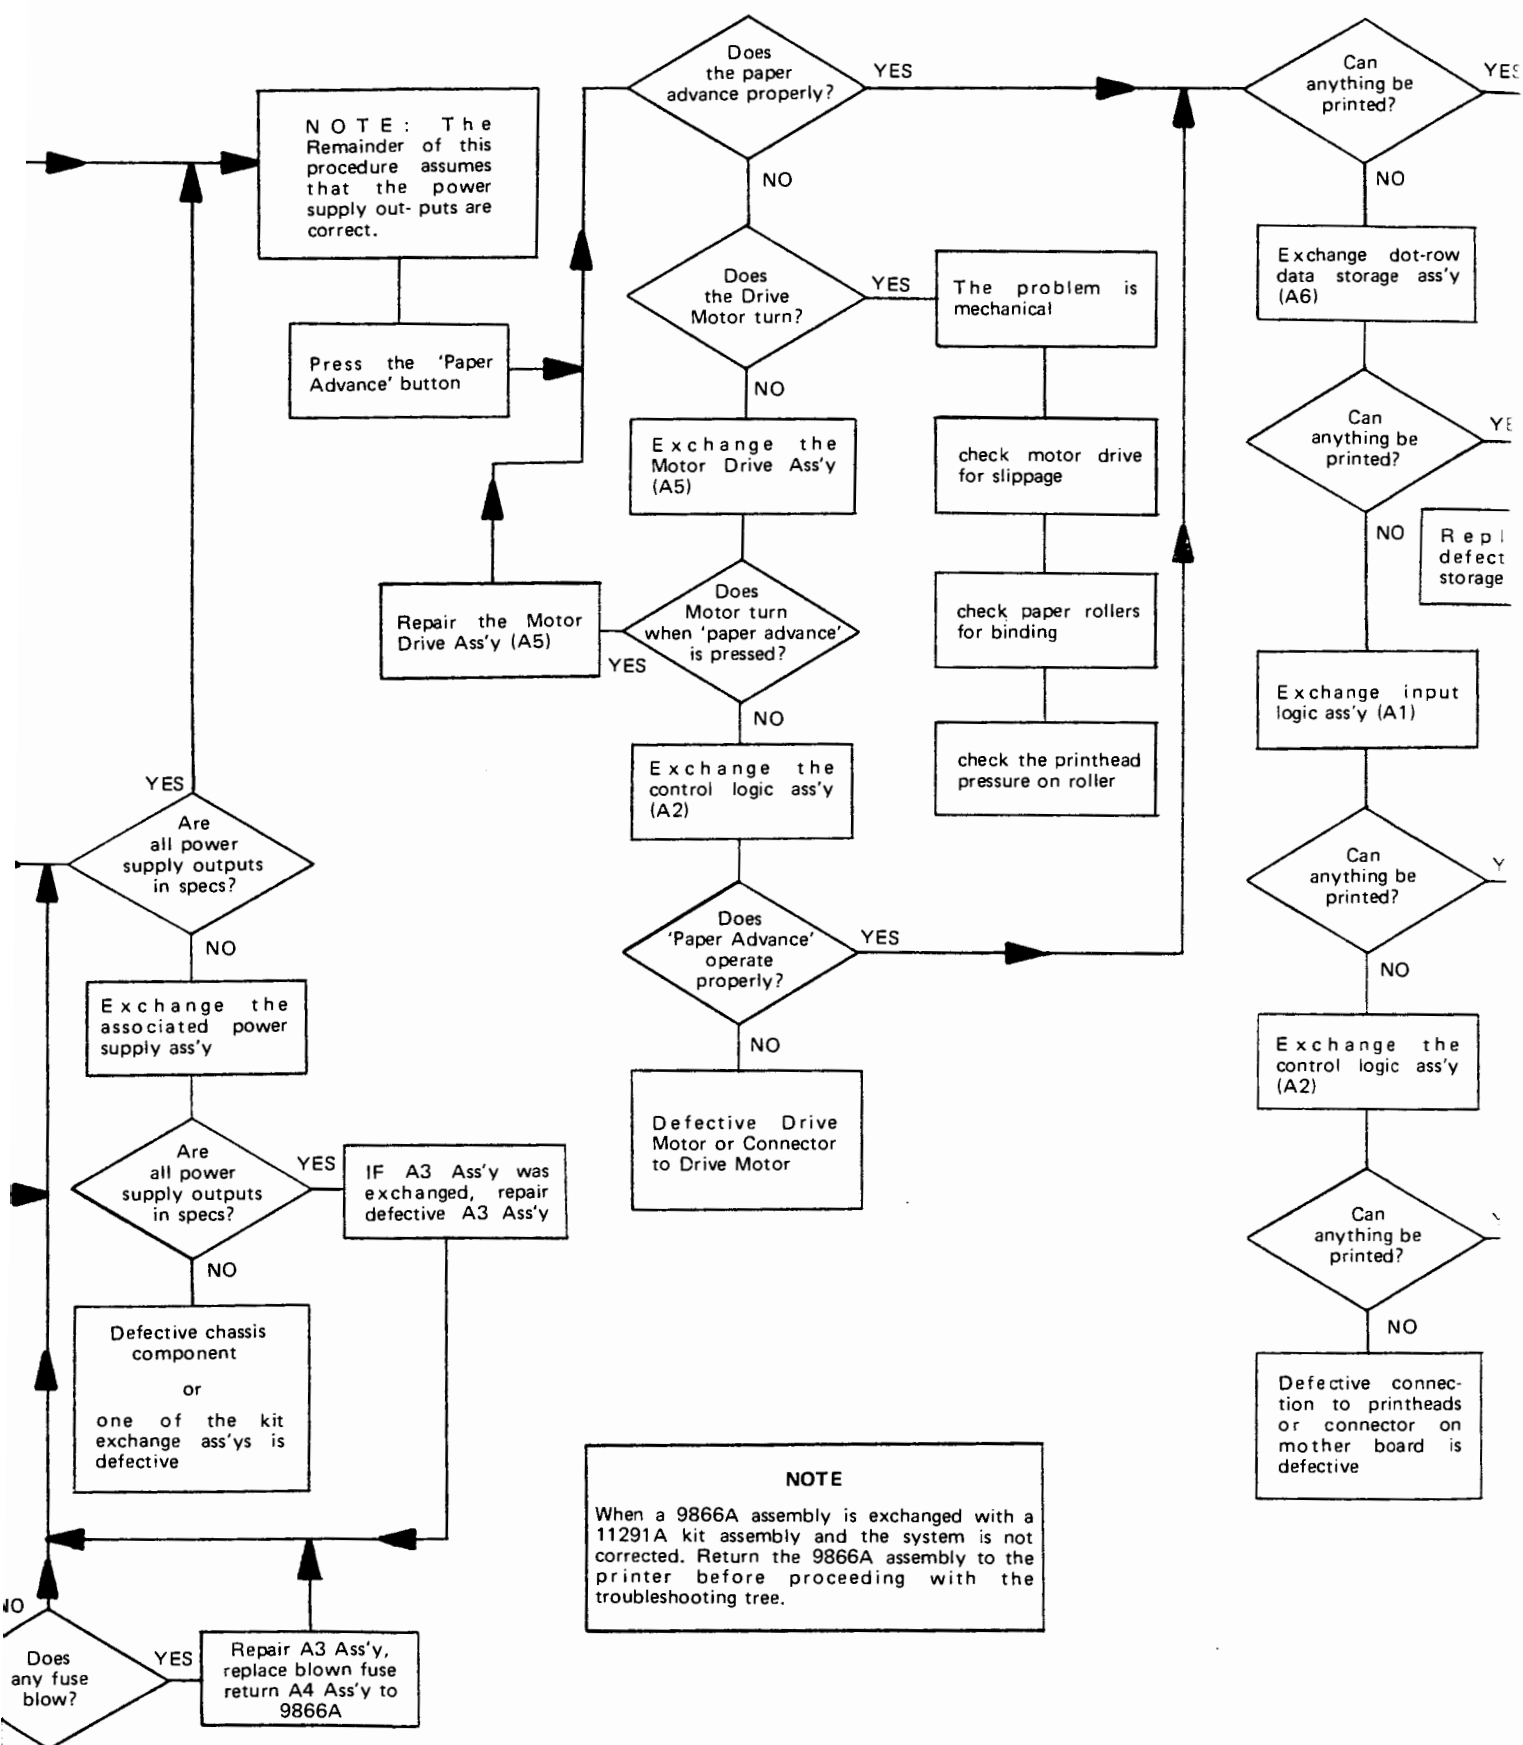

Exchange the control logic ass'y (A1)

NOTE

When a 9866A assembly is exchanged with a 11291A kit assembly and the system is not corrected. Return the 9866A assembly to the printer before proceeding with the troubleshooting tree.

IF A3 Ass'y was exchanged, repair defective A3 Ass'y

Repair A3 Ass'y, replace blown fuse, return A4 Ass'y to 9866
